

a The document: one author, one quarter

one quarter, 2020Q2

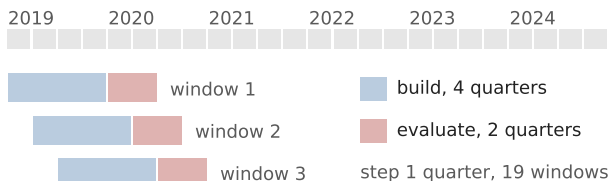

Every ticker an author mentions in a quarter, across all posts and comments, is one document. Two tickers co-mention when a document holds both.

b An eligible pair: should have met, never did

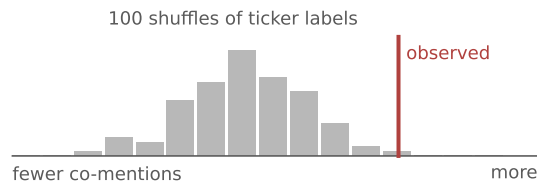

Both tickers are frequent. Had authors picked tickers independently, at least 2 build-period documents would hold both. Observed: none. The pair is eligible; every window has dozens to hundreds of such pairs.

c Rolling windows over 2019 to 2024

Eligible pairs are found in the build period. The statistic counts evaluation-period documents that hold any eligible pair. Build length was chosen by an outcome-blind census rule before any result.

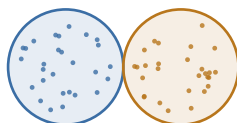

d The statistic: observed count vs. a shuffle null

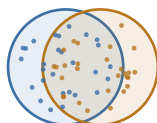

$z = (\text{observed} - \text{shuffle mean}) / \text{shuffle sd}$. z near 0: suppressed pairs meet as often as chance. z far below 0: kept apart, a wall. z above 0: pushed together. Each window has its own null.
